

## **Uncertainty in Measurements: Evaluation of Uncertainty and Errors in Multi-Hole Pressure Probe Measurements**

Every measurement is subject to certain uncertainties. Depending on the measuring instruments and processes in use, small uncertainties, e.g. when calibrating the multi-hole probe, can affect the actual measured results severely. There are various methods for determining the uncertainties of the individual components. In the thesis, all components that can contribute to the measurement uncertainty should be identified and evaluated in a theoretical/mathematical model. This model should be modular in order to allow further extensions. First, the individual components (e.g., sensors, calibration) should be evaluated separately and then in the next step be linked in an overall model of the multi-hole probe.

Preliminary work packages:

1. Familiarization with working principles of multi-hole probes and uncertainty evaluation
2. Development of a model for the estimation of uncertainties and errors
